CPC **E21B 29/005** (2013.01); **E21B 33/13** (2013.01)

A section mill for removing a portion of a casing in a well-bore. The section mill may include a body having a first end portion, a second end portion, and a bore formed axially therethrough. A plurality of blades may be coupled to the body. Each of the blades may have a first end portion and a second end portion. The first end portion of each blade may be coupled to the body via a hinge pin, and the second end portion of each blade may have a cutting surface formed thereon. A seat may be formed within the bore. The blades may be adapted to actuate from an inactive position to an active position in response to an impediment forming a seal against the seat.

EXTENDED DURATION SECTION MILL AND METHODS OF USE

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of a related U.S. Provisional Application Ser. No. 61/677,969 filed Jul. 31, 2012, entitled "Extended Duration Section Mill and Methods of Use," to Stephen Hekelaar, the disclosure of which is incorporated by reference herein in its entirety.

BACKGROUND

When a wellbore is no longer producing, the wellbore may be prepared for abandonment. A segment of the casing is removed to form an openhole section of the wellbore. The openhole section is then plugged, and the wellbore is abandoned. To remove the segment of the casing, a tool string having a section mill coupled thereto is run into the wellbore. Once the section mill reaches the desired depth in the wellbore, fluid pressure is applied to the section mill via the through-bore of the tool string. The fluid pressure causes one or more blades to extend radially outward from the section mill and into contact with the casing. The section mill is rotated about its longitudinal axis (by rotating the tool string) causing the blades to cut through the casing. Once the section mill has cut through the casing, the tool string gradually lowers the section mill, and the blades mill the casing to remove the axial segment thereof.

As the blades mill the axial segment of the casing, the blades become worn down. Accordingly, oftentimes the blades of the section mill are only capable of milling relatively short segments of the casing, e.g., less than about 30 m, before they become worn down and ultimately ineffective. When longer segments of the casing need to be milled, the tool string and section mill are pulled out of the wellbore, a new section mill replaces the worn down section mill, the tool string and the new section mill are run back into the wellbore, and the above process is repeated to continue milling the casing. Replacing the worn down section mill during the milling process is time consuming, which leads to lost profits in the field.

Accordingly, what is needed is an apparatus and method for removing an extended (or longer) axial segment of a casing in a single trip downhole.

SUMMARY

This summary is provided to introduce a selection of concepts that are further described below in the detailed description. This summary is not intended to identify key or essential features of the claimed subject matter, nor is it intended to be used as an aid in limiting the scope of the claimed subject matter.

A section mill for removing a portion of a casing in a wellbore is disclosed. The section mill includes a body having a first end portion, a second end portion, and a bore formed axially therethrough. A plurality of blades may be coupled to the body. Each of the blades has a first end portion and a second end portion. The first end portion of each blade may be coupled to the body via a hinge pin, and the second end portion of each blade may have a cutting surface formed thereon. A seat may be formed within the bore. The blades may be adapted to actuate from an inactive position to an active position in response to an impediment forming a seal against the seat.

2

A downhole tool for removing a portion of a casing in a wellbore is also disclosed. The downhole tool may include a first section mill having a first end portion, a second end portion, and a first axial bore formed therethrough. A first plurality of blades may be coupled to the first section mill. The first plurality of blades each has a first end portion and a second end portion. The first end portion of each of the first plurality of blades may be coupled to the first section mill via a first hinge pin, and the second end portion of each of the first plurality of blades may have a cutting surface formed thereon. A seat may be formed within the first bore. The first plurality of blades may be adapted to actuate from an inactive position to an active position in response to an impediment forming a seal against the seat. A first stabilizer may be coupled to the second end portion of the first section mill. A second axial bore may be formed through the first stabilizer such that the first and second bores are in fluid communication with one another. A second section mill may be coupled to the first stabilizer and have a first end portion, a second end portion, and a third axial bore formed at least partially therethrough. The third bore may be in fluid communication with the first and second bores. A second plurality of blades may be coupled to the second section mill. The second plurality of blades each has a first end portion and a second end portion. The first end portion of each of the second plurality of blades may be coupled to the second section mill via a second hinge pin, and the second end portion of each of the second plurality of blades may have a cutting surface formed thereon.

A method for removing a portion of a casing in a wellbore is also disclosed. The method may include running a downhole tool into the wellbore. The downhole tool may include a first section mill having a first end portion, a second end portion, and a first axial bore formed therethrough. A first plurality of blades may be coupled to the first section mill. The first plurality of blades each has a first end portion and a second end portion. The first end portion of each of the first plurality of blades may be coupled to the first section mill via a first hinge pin, and the second end portion of each of the first plurality of blades may have a cutting surface formed thereon. A seat may be formed within the first bore. The first plurality of blades may be adapted to actuate from an inactive position to an active position in response to an impediment forming a seal against the seat. A first stabilizer may be coupled to the second end portion of the first section mill. A second axial bore may be formed through the first stabilizer such that the first and second bores are in fluid communication with one another. A second section mill may be coupled to the first stabilizer and have a first end portion, a second end portion, and a third axial bore formed at least partially therethrough. The third bore may be in fluid communication with the first and second bores. A second plurality of blades may be coupled to the second section mill. The second plurality of blades each has a first end portion and a second end portion. The first end portion of each of the second plurality of blades may be coupled to the second section mill via a second hinge pin, and the second end portion of each of the second plurality of blades may have a cutting surface formed thereon. The second plurality of blades may be actuated from an inactive position to an active position in response to an increase in pressure in the third bore, and the cutting surfaces of the second plurality of blades may be disposed radially outward from an outer surface of the second section mill in the active position.

BRIEF DESCRIPTION OF THE DRAWINGS

So that the recited features can be understood in detail, a more particular description, briefly summarized above, can

3

be had by reference to one or more embodiments, some of which are illustrated in the appended drawings. It is to be noted, however, that the appended drawings illustrate only exemplary embodiments, and are, therefore, not to be considered limiting of its scope, for the invention can admit to other equally effective embodiments.

FIG. 1 depicts an illustrative downhole tool for removing a segment of a casing in a wellbore, according to one or more embodiments disclosed.

FIG. 2 depicts a partial perspective view of an illustrative first section mill in an inactive position, according to one or more embodiments disclosed.

FIG. 3 depicts a cross-sectional view of the first section mill in the inactive position, according to one or more embodiments disclosed.

FIG. 4 depicts a partial perspective view of the first section mill in an active position, according to one or more embodiments disclosed.

FIG. 5 depicts a cross-sectional view of the first section mill in the active position, according to one or more embodiments disclosed.

FIG. 6 depicts a cross-sectional view of an illustrative second section mill in an inactive position, according to one or more embodiments disclosed.

FIG. 7 depicts a cross-sectional view of the second section mill in an active position, according to one or more embodiments disclosed.

FIG. 8 depicts the downhole tool disposed within the casing of a wellbore, according to one or more embodiments disclosed.

FIG. 9 depicts the blades of the second section mill in the active position, according to one or more embodiments disclosed.

FIG. 10 depicts the blades of the second section mill milling the casing into a first or "upper" segment and a second or "lower" segment, according to one or more embodiments disclosed.

FIG. 11 depicts the blades of the second section mill retracting into the inactive position, according to one or more embodiments disclosed.

FIG. 12 depicts the blades of the first section mill in the active position, according to one or more embodiments disclosed.

FIG. 13 depicts the first section mill milling the casing to increase the length of the axial gap between the first and second segments of the casing, according to one or more embodiments disclosed.

DETAILED DESCRIPTION

FIG. 1 depicts an illustrative downhole tool **100** for removing a segment of a casing in a wellbore, according to one or more embodiments. The downhole tool **100** may include a jet sub **110**, one or more section mills (two are shown **120**, **140**), one or more stabilizers (three are shown **130**, **150**, **170**), and/or a taper mill **180**.

The jet sub **110** may have a bore formed axially therethrough. One or more openings **112** may extend radially through the jet sub **110**. The openings **112** may allow a fluid to flow from the bore of the jet sub **110** to an annulus formed between an exterior of the jet sub **110** and the casing and/or wellbore wall. The openings **112** may include a carbide jet sleeve proximate the outer surface of the jet sub **110**. The openings **112** may be oriented at an angle with respect to a longitudinal axis through the jet sub **110**. More particularly, the portion of the openings **112** proximate the inner surface of the jet sub **110** may be positioned above the portion of the

4

openings **112** proximate the outer surface of the jet sub **110** such that fluid flows in a generally downward direction from the bore, through the openings **112**, and into the annulus. For example, the angle may range from a low of about 10°, about 20°, or about 30° to a high of about 60°, about 70°, or about 80° with respect to vertical.

As used herein, the terms "inner" and "outer"; "up" and "down"; "upper" and "lower"; "upward" and "downward"; "above" and "below"; and other like terms as used herein refer to relative positions to one another and are not intended to denote a particular direction or spatial orientation. The terms "couple," "coupled," "connect," "connection," "connected," "in connection with," and "connecting" refer to "in direct connection with" or "in connection with via one or more intermediate elements or members."

A first section mill or "extended duration" section mill **120** may be coupled to the lower end portion of the jet sub **110**. The first section mill **120** may have a bore formed axially therethrough that is in fluid communication with the bore formed through the jet sub **110**. One or more cutters or blades (three are shown **210**, **220**, **230**; one is obscured **240**) may be coupled to the first section mill **120**. For example, the number of blades **210**, **220**, **230**, **240** may range from a low of about 1, 2, 3, or 4 to a high of about 6, 8, 10, 12, or more. The blades **210**, **220**, **230**, **240** may be circumferentially and/or axially offset on the first section mill **120**. The blades **210**, **220**, **230**, **240** may be adapted to move or pivot radially outward toward the casing in the wellbore. The blades **210**, **220**, **230**, **240** may be shaped, sized, and dressed to remove an extended section of the casing. The first section mill **120** is discussed in more detail below with reference to FIGS. 2-5.

A first stabilizer **130** may be coupled to the lower end portion of the first section mill **120**. The first stabilizer **130** may have a bore formed axially therethrough that is in fluid communication with the bores formed through the jet sub **110** and the first section mill **120**. One or more blades (three are shown **132**, **134**, **136**) may be coupled to or integrated with an outer surface of the first stabilizer **130**. The blades **132**, **134**, **136** may be straight or spiraled (as shown). The blades **132**, **134**, **136** may be made of a hard metal, such as steel. Further, the blades **132**, **134**, **136** may be coated with a hard hardfacing material, such as tungsten carbide or the like. The first stabilizer **130** may be adapted to mechanically stabilize the first section mill **120** and/or the downhole tool **100** within the casing to avoid unintentional sidetracking and/or lateral vibrations. For example, the first stabilizer **130** may be adapted to maintain a longitudinal centerline through the first section mill **120** and/or the downhole tool **100** in alignment with a longitudinal centerline through the casing.

A second section mill **140** may be coupled to the lower end portion of the first stabilizer **130**. The second section mill **140** may be the same as the first section mill **120**, i.e., an "extended duration" section mill, or the second section mill **140** may be another type of section mill known to those skilled in the art. The second section mill **140** may have a bore formed at least partially therethrough that is in fluid communication with the bores formed through the jet sub **110**, the first section mill **120**, and the first stabilizer **130**. One or more cutters or blades (three are shown **310**, **320**, **330**; one is obscured **340**) may be coupled to the second section mill **140**. For example, the number of blades **310**, **320**, **330**, **340** may range from a low of about 1, 2, 3, or 4 to a high of about 6, 8, 10, 12, or more. The blades **310**, **320**, **330**, **340** may be circumferentially and/or axially offset on the second section mill **140**. The blades **310**, **320**, **330**, **340** may be adapted to move or pivot radially outward toward the casing in the wellbore. The blades **310**, **320**, **330**, **340** may be shaped, sized, and dressed to first

5

initiate the cut and subsequently remove a section of the casing. The second section mill **140** is discussed in more detail below with reference to FIGS. **6** and **7**.

A second stabilizer **150** may be coupled to the lower end portion of the second section mill **140**. The second stabilizer **150** may be the same as the first stabilizer **130**, or the second stabilizer **150** may be another type of section mill known to those skilled in the art. The second stabilizer **150** may be adapted to mechanically stabilize the second section mill **140** and/or the downhole tool **100** within the casing to avoid unintentional sidetracking and vibrations. For example, the second stabilizer **150** may be adapted to maintain a longitudinal centerline through the second section mill **140** and/or the downhole tool **100** in alignment with a longitudinal centerline through the casing.

A tail pipe **160** may be coupled to the lower end portion of the second stabilizer **150**. The tail pipe **160** may be a blank section of pipe having a length ranging from a low of about 1 m, about 2 m, or about 3 m to a high of about 10 m, about 20 m, about 30 m, or more.

A third stabilizer **170** or a taper mill **180** may be coupled to the lower end portion of the tail pipe **160**. When the casing is cut into two axially offset segments, e.g., upper and lower segments, the third stabilizer **170** or the taper mill **180** may be disposed within the lower segment of the casing to mechanically stabilize the downhole tool **100** within the lower segment of the casing to avoid unintentional sidetracking and vibrations. For example, the third stabilizer **170** or the taper mill **180** may be adapted to maintain a longitudinal centerline through the downhole tool **100** in alignment with a longitudinal centerline through the lower segment of the casing.

FIG. **2** depicts a partial perspective view of the first section mill **120** in an inactive position, and FIG. **3** depicts a cross-sectional view of the first section mill **120** in the inactive position, according to one or more embodiments. The first section mill **120** includes an annular body **200** with a first or "upper" end portion **202** and a second or "lower" end portion **204**. A bore **206** may extend through the body **200** and provide a path of fluid communication from the first end portion **202** to the second end portion **204**.

The blades **210**, **240** (blades **220**, **230** not shown) are coupled to the body **200** of the first section mill **120**. For example, a first end portion **212**, **242** of each blade **210**, **240** may be movably coupled to the body **200** with a hinge pin **214**, **244** or other coupling device known to those skilled in the art which permits the blade **210**, **240** to pivot relative to the body **200**. A second end portion **216**, **246** of each blade **210**, **240** may have a cutting surface **218**, **248** formed or disposed thereon. The cutting surfaces **218**, **248** may be adapted to cut, grind, or otherwise mill the casing, as described in more detail below. The same disclosure herein with respect to first and second blades **210**, **240** equally applies to the other blades, e.g., **220**, **230**, of the first section mill **120**.

While the second end portions **216**, **246** of the blades **210**, **240** may be axially adjacent to one another, the first end portions **212**, **242** of the blades **210**, **240** may be axially offset from one another. This may prevent the hinge pins **214**, **244** from intersecting or otherwise interfering with one another. As such, the blades **210**, **240** may have different lengths, as shown.

The first and second blades **210**, **240** in FIGS. **2** and **3** are shown in an inactive position. In the inactive position, the second end portions **216**, **246** of the blades **210**, **240**, and the cutting surfaces **218**, **248** formed thereon, are folded into the body **200** of the first section mill **120** such that an outer surface of the blades **210**, **240** is aligned with an outer surface

6

of the body **200**. Accordingly, the blades **210**, **240** are not capable of cutting, grinding, or otherwise milling the casing in the inactive position.

The first and second blades **210**, **240** may be secured in the inactive position via engagement with one or more axial protrusions **282** extending from a first piston **280** in the body **200**. The axial protrusions **282** may include a sloped surface **284**. The sloped surface **284** may be oriented at an angle with respect to a longitudinal centerline through the first section mill **120**. The angle may be from about 0° (parallel with the centerline) to about 10°, about 10° to about 30°, about 30° to about 45°, about 45° to about 60°, or about 60° to about 80°. The sloped surface **284** may be arranged and designed to mate with, abut, or otherwise contact the cutting surfaces **218**, **248** of the first and second blades **210**, **240** to secure the first and second blades **210**, **240** in the inactive position.

FIG. **4** depicts a partial perspective view of the first section mill **120** in an active position, and FIG. **5** depicts a cross-sectional view of the first section mill **120** in the active position, according to one or more embodiments. The first section mill **120** may include a seat or "ball seat" **250** formed therein. For example, the seat **250** may be a transition or shoulder formed by a decrease in the diameter of the bore **206**. The seat **250** may be positioned between the blades **210**, **240** and the second end portion **204** of the body **200**.

The seat **250** may be adapted to receive an impediment **252** that enters the bore **206** of the first section mill **120** through the first end portion **202** thereof. The impediment **252** may be a ball, a dart, or the like. For example, the impediment **252** may be a steel ball. The impediment **252** is arranged and designed to form a fluid tight seal against the seat **250** enabling one-way fluid flow through the bore **206**. More particularly, fluid may flow through the bore **206** from the second end portion **204** toward the first end portion **202** (i.e., upward); however, fluid flowing through the bore **206** from the first end portion **202** toward the second end portion **204** (i.e., downward) may be directed out into the annulus via ports **260**, **262**, as explained in more detail below.

When the impediment **252** is received and seated in the seat **250**, the bore **206** is blocked, and the pressure of the fluid in the bore **206** above the ball **252** begins to increase. The pressure of the fluid in bore **206** increases to a point which causes the first piston **280** and a second piston **270** to move toward the second end portion **204** (i.e., downward), thereby shearing shear pins **272**, **274** and compressing a spring **254**. When the first piston **280** moves a predetermined distance, the axial protrusions **282** (if present) may disengage and become axially offset from the cutting surfaces **218**, **248** of the first and second blades **210**, **240**. A cam or wedge **276** on the second piston **270** may then move or pivot the blades **210**, **240** (and also blades **220**, **230**) outwardly about the hinge pins **214**, **244** into an active position. In the active position, the second end portions **216**, **246** of the blades **210**, **240**, and the cutting surfaces **218**, **248** formed thereon, are positioned radially outward from the outer surface of the body **200** of the first section mill **120**. Accordingly, the blades **210**, **240** (and blades **220**, **230**) are adapted to cut, grind, or mill the casing (which is disposed radially outward from the body **200** of the first section mill **120**) in the active position.

One or more openings or ports **260**, **262** may be formed radially through the body **200**. A first opening **260** may be disposed proximate the first end portion **202** of the body **200**. For example, the first opening **260** may be disposed between the first end portion **202** of the body **200** and the blades **210**, **240**. When the piston **270** is moved downwardly as shown in FIGS. **4** and **5** (and as disclosed above), the first opening **260** is exposed and provides a path for fluid to travel between bore

7

206 and the annulus formed between the outer surface of the body 200 and the casing and/or wellbore wall. A second opening or port 262 may be disposed proximate the second end portion 204 of the body 200. For example, the second opening 262 may be disposed between the second end portion 204 of the body 200 and the blades 210, 240 and/or the seat 250. When the piston 270 is moved downwardly as shown in FIGS. 4 and 5, an opening 264 in the wall of piston 270 may come into axial alignment with the second opening 262 and provide a path for fluid to travel between bore 206 and the annulus formed between the outer surface of the body 200 and the casing and/or wellbore wall.

As the blades 210, 240 actuate back into the inactive position by folding inward, the first and second pistons 280, 270 may move toward the second end portion 204, once again compressing the spring 254. After the blades 210, 240 have moved inward, the first and second pistons 280, 270 may move back toward the first end portion 202, and the sloped surfaces 284 of the axial protrusions 282 (if present) may reengage the corresponding cutting surfaces 218, 248 of the first and second blades 210, 240 to secure the first and second blades 210, 240 in the inactive position.

FIG. 6 depicts a cross-sectional view of the second section mill 140 in an inactive position, and FIG. 7 depicts a cross-sectional view of the second section mill 140 in an active position, according to one or more embodiments. The second section mill 140 includes a body 300 with a first or "upper" end portion 302 and a second or "lower" end portion 304. A bore 306 extends through the body 300, but as will be disclosed in greater detail below, is occluded when the second section mill 140 is in its inactive position.

The blades 310, 340 (blades 320, 330 not shown) may be movably coupled to the body 300 of the second section mill 140 via hinge pins 314, 344 or other coupling devices known to those skilled in the art which permits the blade 310, 340 to pivot relative to the body 300. The blades 310, 340 may be generally similar to the blades 210, 240 of the first section mill 120 described above. The first and second blades 310, 340 of the second section mill 140 are shown in an inactive position in FIG. 6 and in an active position in FIG. 7. In the inactive position, the blades 310, 340 are not capable of cutting, grinding, or otherwise milling the casing. The same disclosure herein with respect to blades 310, 340 equally applies to the other blades, e.g., 320, 330, of the second section mill 140.

Rather than a ball seat 250 (as shown in FIGS. 2-5), the second section mill 140 may include a valve such as the FLO-TEL® assembly 350 manufactured and sold by Schlumberger Limited. As best shown in FIG. 7, the FLO-TEL assembly 350 is adapted to permit fluid flow through openings 352 and around a stinger 372 to move a piston 370 axially within the bore 306 in response to an increased pressure of the fluid in the bore 306. When the pressure of the fluid in the bore increases to a predetermined level, the piston 370 moves or actuates, thereby causing the blades 310, 340, which are couple thereto, to move or pivot into the active position. The first section mill 120 may alternatively have a valve, such as the FLO-TEL® assembly 350 disclosed above, rather than a ball seat 250. Such a valve in the first section mill 120 may be arranged and designed to be responsive to a different (e.g., higher) bore fluid pressure than the valve of the second section mill 140 in order to permit independent actuation of the first and second section mills 120, 140. In one or more embodiments, the second section mill 140 may have an arrangement (not shown), e.g., ball seat 250, first/second pistons 270, 280, shear pins 272, 274 and spring 254, similar to that disclosed with respect to first section mill 120. Such

8

arrangement may have a ball seat which is smaller in size to seat a smaller ball. Accordingly, the smaller ball is arranged and designed to pass through the ball seat 250 of the first section mill 120.

FIGS. 8-13 depict an exemplary process for removing a segment of a casing 410 in a wellbore 400. More particularly, FIG. 8 depicts the downhole tool 100 disposed within the casing 410 of the wellbore 400, according to one or more embodiments. In operation, the downhole tool 100 is run into the wellbore 400 with a tool string 420 to the desired depth. As the downhole tool 100 is being run into the wellbore 400, the blades 210, 220, 230, 240, 310, 320, 330, 340 on the first and second section mills 120, 140 may be in the inactive, i.e., folded-in, position.

FIG. 9 depicts the blades 310, 320, 330, 340 (340 not shown in FIGS. 9-11) of the second section mill 140 in the active position, according to one or more embodiments. Once the downhole tool 100 reaches the desired depth, pressure may be applied to the tool string 420 from the surface via a pumped fluid. When the pressure reaches a predetermined level within the downhole tool 100, piston 370 (see FIGS. 6 and 7) in the second section mill 140 actuates the blades 310, 320, 330, 340 of the second section mill 140 into the active position such that they are in contact with the casing 410.

FIG. 10 depicts the blades 310, 320, 330, 340 of the second section mill 140 milling the casing 410 into a first or "upper" segment 412 and a second or "lower" segment 414, according to one or more embodiments. The tool string 420 and downhole tool 100 may be rotated in any manner known to those skilled in the art, thereby causing the blades 310, 320, 330, 340 to cut through the casing 410. Once the blades 310, 320, 330, 340 have cut through the casing 410, the tool string 420 may gradually lower the downhole tool 100 within the wellbore 400. As the downhole tool 100 moves downward, the blades 310, 320, 330, 340 of the second section mill 140 grind or mill the casing 410 to remove a portion thereof, thereby forming the first or "upper" segment 412 and the second or "lower" segment 414 with a removed portion or "axial gap" 416 disposed therebetween. In at least one embodiment, the length of the axial gap 416 created by the second section mill 140 may range from a low of about 5 m, about 10 m, or about 15 m to a high of about 20 m, about 30 m, about 40 m, or more.

FIG. 11 depicts the blades 310, 320, 330, 340 of the second section mill 140 retracting into the inactive position, according to one or more embodiments. In at least one embodiment, milling the casing 410 causes the blades 310, 320, 330, 340 of the second section mill 140 to become worn down and less effective. As such, an operator at the surface may retract the blades 310, 320, 330, 340 of the second section mill into the inactive position. To retract the blades 310, 320, 330, 340, the pressure applied to the tool string 420 may be decreased. As the pressure decreases, spring 354 (see FIGS. 6 and 7) biases the blades 310, 320, 330, 340 from the active position to the inactive position.

To ensure that the blades 310, 320, 330, 340 retract into the inactive position, the tool string 420 may be pulled upward, thereby pulling the downhole tool 100 upward within the wellbore 400. As the blades 310, 320, 330, 340 contact the first segment 412 of the casing 410, the first segment 412 applies a downward force on the outer surface of the blades 310, 320, 330, 340 causing them to rotate about the hinge pins 314, 344 and into the inactive position. As this occurs, the tail pipe 160 may be long enough so that the third stabilizer 170 (as shown) or the taper mill 180 (see FIG. 1) remains disposed within the second segment 414 of the casing 410. This ensures that the downhole tool 100 is properly aligned within the

second segment **414** of the casing **410** when the downhole tool **100** is lowered within the wellbore **400** again.

FIG. 12 depicts the blades **210**, **220**, **230**, **240** (**240** not shown in FIGS. 12-13) of the first section mill **120** in the active position, according to one or more embodiments. The first section mill **120** may be used to increase the length of the axial gap **416** between the first and second segments **412**, **414**. Once the blades **310**, **320**, **330**, **340** of the second section mill **140** have actuated to their inactive position, the tool string **420** may lower the downhole tool **100** to a position in the wellbore **400** where the first section mill **120** is aligned with the axial gap **416** in the casing **410**.

An impediment **252** may then be inserted into the tool string **420** from an operator at the surface. The impediment **252** travels through the through-bore of the tool string **420** and into the downhole tool **100** where it comes to rest against the seat **250** in the first section mill **120** forming a fluid tight seal therewith. Pressure may then be applied to the fluid in the through-bore of the tool string **420** from the surface via a pumped fluid. Due to the seal, the pressure will continue to rise up to the level where it exceeds the collective resistance of the shear pins **272**, **274**. This pressure level may range from a low of about 6 MPa, about 8 MPa, or about 10 MPa to a high of about 12 MPa, about 14 MPa, about 16 MPa, or more. This higher pressure causes shear pins **272**, **274** within the first section mill **120** to shear, thereby permitting the piston **270** to be moved downward. Downward movement of the piston **270** moves or pivots the blades **210**, **220**, **230**, **240** outwardly into an active position (via cam or wedge **276**) and provides a path of fluid communication between the bore **206** of the first section mill **120** and the exterior of the first section mill **120** via the openings **260** and/or **262**, as previously disclosed. Such fluid communication between the bore **206** and the annulus causes the pressure in the bore **206** to drop to a level ranging from a low of about 1 MPa, about 1.5 MPa, or about 2 MPa to a high of about 2.5 MPa, about 3 MPa, about 3.5 MPa, or more. This lower pressure maintains the actuation of the blades **210**, **220**, **230**, **240** of the first section mill **120** in their active position, as shown in FIG. 12.

FIG. 13 depicts the first section mill **120** milling the casing **410** to increase the length of the axial gap **416** between the first and second segments **412**, **414** of the casing **410**, according to one or more embodiments. The tool string **420** may then lower the downhole tool **100** within the wellbore **400** until the blades **210**, **220**, **230**, **240** of the first section mill **120** contact the upper end portion of the second segment **414**. The tool string **420** may then continue to gradually lower the downhole tool **100** within the wellbore **400**. The rotation of the downhole tool **100** causes the blades **210**, **220**, **230**, **240** to grind or mill the second segment **414** of the casing **410**, thereby increasing the length of the axial gap **416** in the casing **410**.

In at least one embodiment, the length of the axial gap **416** in the casing **410** removed by the first section mill **120** may range from a low of about 5 m, about 10 m, or about 15 m to a high of about 20 m, about 30 m, about 40 m, or more. Thus, the length of the axial gap **416** in the casing **410** created by the first and second section mills **120**, **140** may range from a low of about 10 m, about 20 m, or about 30 m to a high of about 50 m, about 75 m, about 100 m, about 125 m, or more. In addition, one or more additional first section mills (not shown) may be coupled to or integrated with the downhole tool **100** and used to further increase the length of the axial gap **416** in the casing **410**.

When the desired length of the axial gap **416** in the casing **410** is reached, or the blades **210**, **220**, **230**, **240** of the first section mill **120** become worn down, the operator may decrease the pressure of the fluid applied from the surface. As

the pressure of the fluid in the bore **206** of the first section mill **120** decreases, the one or more springs **254** may actuate the blades **210**, **220**, **230**, **240** from the active position to the inactive position. The tool string **420** may then be pulled upwardly, thereby pulling the downhole tool **100** upward and out of the wellbore **400**. If the desired axial gap length has been achieved, cement may then be introduced into the open-hole portion of the wellbore **400**, i.e., between the first and second segments **412**, **414** of the casing **410**, to form a plug or barrier above a previously installed bridge plug. Once the cement plug is in place, the wellbore **400** may be considered abandoned.

Although only a few example embodiments have been described in detail above, those skilled in the art will readily appreciate that many modifications are possible in the example embodiments without materially departing from "Extended Duration Section Mill and Methods of Use." For instance, in several of the Figures, the first section mill **120** is shown positioned above the second section mill **140**; however, those skilled in the art will appreciate that in one or more embodiments the second section mill **140** may be positioned above the first section mill **120**. Accordingly, all such modifications are intended to be included within the scope of this disclosure. In the claims, means-plus-function clauses are intended to cover the structures described herein as performing the recited function and not only structural equivalents, but also equivalent structures. Thus, although a nail and a screw may not be structural equivalents in that a nail employs a cylindrical surface to secure wooden parts together, whereas a screw employs a helical surface, in the environment of fastening wooden parts, a nail and a screw may be equivalent structures. It is the express intention of the applicant not to invoke 35 U.S.C. § 112, paragraph 6 for any limitations of any of the claims herein, except for those in which the claim expressly uses the words "means for" together with an associated function.

What is claimed is:

1. A section mill for removing a portion of a casing in a wellbore, comprising:

a body having a first end portion, a second end portion, and a bore formed axially therethrough;

a plurality of blades each having a first end portion and a second end portion, wherein the first end portion of each blade is movably coupled to the body, and the second end portion of each blade has a cutting surface disposed thereon;

at least two pistons within the bore of the body, a first of the at least two pistons being axially between the second of the at least two pistons and the second end portion of the body;

a cam coupled to the second of the at least two pistons and adapted to be moved axially within the bore of the body by the second of the at least two pistons; and

a seat formed within the bore and coupled to the first of the at least two pistons, the seat being axially between the second end portions of the plurality of blades and the second end portion of the body, wherein the plurality of blades are adapted to actuate from an inactive position to an active position in response to the cam moving axially within the bore and engaging the plurality of blades, the cam being movable in response to a fluid pressure increase moving the second of the at least two pistons in response to an impediment entering the body through the first end portion, moving axially past the second of the at least two pistons, and forming a seal against the

11

seat, the plurality of blades being adapted to actuate to the active position while the impediment remains seated on the seat.

2. The section mill of claim 1, further comprising the impediment disposed within the bore and against the seat.

3. The section mill of claim 1, wherein the impediment is a ball.

4. The section mill of claim 1, wherein the cutting surfaces of the blades are disposed radially outward from an outer surface of the body in the active position.

5. The section mill of claim 1, further comprising at least one radial opening formed in the body and providing a path of fluid communication between the bore and an outer surface of the body when the plurality of blades are in the active position, one or more of the at least two pistons blocking the path of fluid communication when the plurality of blades are in the inactive position.

6. The section mill of claim 5, wherein the at least one radial opening is positioned axially between the first end portion of the body and the blades.

7. The section mill of claim 5, wherein the at least one radial opening is positioned axially between the second end portion of the body and the blades.

8. The section mill of claim 1, wherein the blades are shaped, sized, and dressed to remove a portion of casing.

9. The section mill of claim 1, a bias element maintaining the first of the at least two pistons at a first position when the plurality of blades are in the inactive position, and a shear element maintaining the second of the at least two pistons at a first position when the plurality of blades are in the inactive position.

10. A downhole tool for removing a portion of a casing in a wellbore, comprising:

a first section mill having a body with a first end portion, a second end portion, and a first axial bore formed therethrough, the first section mill including:

a first plurality of blades each having a first end portion and a second end portion, wherein the first end portion of each of the first plurality of blades is movably coupled to the body of the first section mill, and the second end portion of each of the first plurality of blades has a cutting surface disposed thereon;

a first piston located within the first axial bore, the first piston being movable within the first axial bore in response to fluid pressure in the first axial bore;

a second piston located within the first axial bore, the second piston being coupled to a cam that is moved axially within the first axial bore by the second piston and in response to fluid pressure in the first axial bore, the second piston being positioned axially between the first piston and the first end portion;

a seat formed within the first bore and coupled to the first piston, wherein the first plurality of blades is adapted to actuate from an inactive position to an active position in response to the cam moving axially within the first axial bore to engage the first plurality of blades, the second piston being adapted to move the cam in response to a fluid pressure change resulting from an impediment moving within the body away from the second piston and toward the first piston until forming a seal against the seat, the plurality of blades being adapted to actuate to the active position while the impediment remains seated on the seat;

a first stabilizer coupled to the second end portion of the body of the first section mill, wherein a second axial bore

12

is formed through the first stabilizer such that the first and second bores are in fluid communication with one another; and

a second section mill coupled to the first stabilizer and having a body with a first end portion, a second end portion, and a third axial bore formed at least partially therethrough, wherein the third bore is in fluid communication with the first and second bores, the second section mill including:

a second plurality of blades each having a first end portion and a second end portion, wherein the first end portion of each of the second plurality of blades is moveably coupled to the body of the second section mill, and the second end portion of each of the second plurality of blades has a cutting surface disposed thereon; and

at least a third piston in the third axial bore, the third piston being movable within the third axial bore in response to fluid pressure in the third axial bore to move the second plurality of blades from an inactive position to an active position.

11. The downhole tool of claim 10, further comprising a jet sub coupled to the first end portion of the body of the first section mill, wherein the jet sub includes a fourth axial bore formed therethrough that is in fluid communication with the first, second, and third bores, and wherein at least one radial opening forms a path of fluid communication between the fourth bore and an outer surface of the jet sub.

12. The downhole tool of claim 10, further comprising a second stabilizer coupled to the second end portion of the body of the second section mill.

13. The downhole tool of claim 10, further comprising a valve disposed within the third bore, and wherein third piston is adapted to move and the second plurality of blades is adapted to actuate from an inactive position to an active position in response to movement of the valve.

14. The downhole tool of claim 10, further comprising a valve disposed within the third bore, wherein the valve causes an increase in a pressure of a fluid forcing the second plurality of blades to cut into the casing and subsequently remove the portion of the casing.

15. A method for removing a portion of a casing in a wellbore, comprising:

running a downhole tool into the wellbore, wherein the downhole tool includes:

a first section mill having:

a body having a first end portion, a second end portion, and a first axial bore formed therethrough;

a first plurality of blades each having a first end portion and a second end portion, wherein the first end portion of each of the first plurality of blades is movably coupled to the body of the first section mill, and the second end portion of each of the first plurality of blades has a cutting surface disposed thereon; and

first and second pistons within the first axial bore, the second piston including a cam for engaging the first plurality of blades and the first piston being coupled to a seat formed within the first axial bore, wherein the first plurality of blades are adapted to actuate from an inactive position to an active position in response to an impediment moving away from the second piston and toward the first piston until forming a seal against the seat, and remaining seated on the seat, thereby allowing fluid pressure to build to move the second piston and cam axially against the first plurality of blades;

13

a stabilizer coupled to the second end portion of the body of the first section mill, wherein a second axial bore is formed through the stabilizer such that the first and second bores are in fluid communication with one another; and

a second section mill coupled to the stabilizer and having:

- a body with a first end portion, a second end portion, and a third axial bore formed at least partially there-through, wherein the third bore is in fluid communication with the first and second bores;
- a second plurality of blades each having a first end portion and a second end portion, wherein the first end portion of each of the second plurality of blades is movably coupled to the second section mill, and the second end portion of each of the second plurality of blades has a cutting surface disposed thereon; and
- at least a third piston in the third axial bore, the at least a third piston being movable within the third axial bore in response to fluid pressure in the third axial bore to move the second plurality of blades from an inactive position to an active position; and

actuating the second plurality of blades from an inactive position to an active position in response to an increase in pressure in the third bore, wherein the cutting surfaces of the second plurality of blades are disposed radially outward from an outer surface of the second section mill in the active position.

16. The method of claim 15, further comprising:
rotating the downhole tool such that the second plurality of blades removes a first portion of casing, thereby forming first and second segments of the casing having an axial gap disposed therebetween; and

14

actuating the second plurality of blades from the active position to the inactive position after the axial gap has been formed.

17. The method of claim 16, further comprising moving the downhole tool axially within the wellbore to align the first plurality of blades of the first section mill with the axial gap in the casing, and using the first plurality of blades to extend an axial length of the axial gap.

18. The method of claim 17, further comprising:
dropping the impediment into the first bore of the body of the first section mill such that the impediment passes through the second piston and forms a seal against the seat;

while the impediment forms the seal against the seat, actuating the first plurality of blades from the inactive position to the active position in response to an increase in pressure in the first bore; and
rotating the downhole tool such that the first plurality of blades removes a second portion of the casing, thereby increasing a length of the axial gap disposed between the first and second segments of the casing.

19. The method of claim 18, wherein actuating the second plurality of blades includes flowing fluid through the first axial bore and the second axial bore to the third axial bore, and wherein actuating the first plurality of blades includes increasing the fluid pressure above a shear value of one or more shear elements coupling the first piston to the body of the first section mill.

20. The method of claim 16, the downhole tool further including at least a second stabilizer below the first and second section mills, the method further comprising:

moving the downhole tool axially within the wellbore to align the second plurality of blades of the second section mill with the casing above the gap while maintaining the second stabilizer aligned with the casing below the gap.

* * * * *
